

symmetry
creates a wall

WHAT AN OPTICAL SENSOR CANNOT SEE

calibration measures
its blindness capacity

tangent dimension sets
what is certifiable

Two exact walls

SUPPORT wall
hard-pupil field, kerA
null 6.6×10^{-16}

breaker → finite window (leak law)
5%

ENERGY wall
 $E \rightarrow UE$, full bucket
null 2.2×10^{-16}

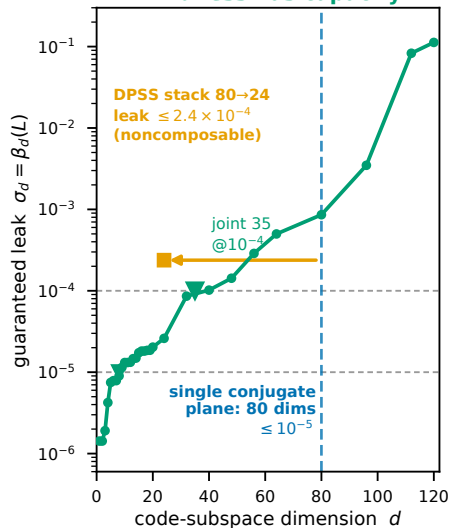

breaker → NA clipping
 $\varepsilon^{1.00}$

score-null orbits

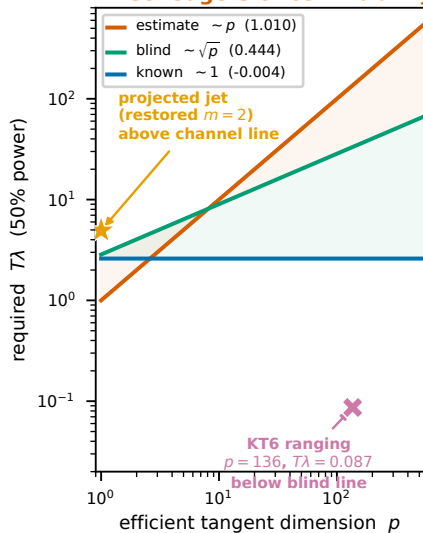

$$\mathbf{P}_g \cdot \mathbf{x} = \mathbf{P}_x \Rightarrow \mathbf{I}_x \mathbf{X}_\xi = \mathbf{0}$$

no data volume, moment order, or
prior recovers an orbit direction

Blindness has capacity

Three ledgers of certifiability

$\beta_d(L) = \sigma_d(L)$ — and does not automatically compose

$1 : \sqrt{p} : p$ — a nonzero signal is not a certifiable signal
